

PRD - Template-Based Production Planning

Product Requirements Document · portfolio sample. Company, client, and product names have been genericized; structure and logic are unchanged.

- **Status:** Draft — re-baselined to the template model (3.3 rev 40); single planning flow; Revenue, buffer, and Daily Target all deferred (platform-first V1)
- **Owner:** Jauhar Nurandyo
- **Epic:** Project Brief - EPIC 3 - Production Planning
- **Phase:** P1 · the planning layer — the SM flow that turns the day's templates into a plan and its Production Orders
- **Tenant scope:** the client — QSR chain, QSR-company whitelisted
- **Model:** exit-only deduction (EPIC 2) — stock deducts at **sale and waste** via BOM explosion; production banks onto the **produced output** — an FG or a produced SFG — at the actual entry (3.1). The plan writes intent only; no stock movement ever leaves the planning surface
- **Surface:** outlet-side planning form (SM) — **Setup** -> **per-template targets** -> **Submit** — plus the plan tableview; submit creates the **Production Orders**

1. Objective

Give the Store Manager one flow to build a day's production plan: fix **branch and dates**, and every plannable **template** autofills from the computed reference day (sales counted through each template's menu members, converted by Qty BOM), adjust the slotted quantities, and **submit** — locking the plan, snapshotting its definitions, and creating the **Production Orders** the KDS runs on. One basis, one flow: quantities from the reference day. The Daily Target field, the revenue/buffer lever, and weekly generation are all **deferred but planned** — V1 builds the core platform (§9).

The plan writes **no stock movement** — planning is a paper act. Deduction belongs to the exits (sale and waste, EPIC 2); production banks stock at the actual entry (3.1); nothing on this surface touches a ledger.

Scope boundary. This PRD is the SM's planning flow: Setup, the reference-day autofill through the template mapping, per-slot editing, the read-only Raw Material preview, submit-to-Production-Orders, and the tableview. It is **not** the template definition (3.3), **not** the actual entry (3.1), **not** the buffer/suggest-buffer computation, the Daily Target Sales field itself, or H+7 generation (all **deferred** — PP-05/07 land with 3.4), and **not** the Revenue planning basis (**deferred**; the retired two-basis wizard is superseded — §9). It embeds no procurement: the Raw Material step informs and routes; it never raises a PR/PO, never reserves stock, never blocks a submit. BRD anchors: **PP-04..07** (sales source, generation parameters, output list, buffer — generation parts deferred as noted), **PP-13** (movement contract, EPIC 2/3.1's side).

2. Problem Statements

- Without a written plan, cook decisions live in the SM's head — nothing for the actual (3.1) to diverge from, and plan-vs-actual (PP-12) has no baseline.
- The best cheap predictor of today is the same day-of-week, same week-of-month, one month back — but converting that day's sales into cook quantities **per template, through its menu members**, is arithmetic nobody does consistently by hand.
- A plan can demand more material than the outlet effectively holds; today the shortfall surfaces at the fryer, mid-rush — too late to receive or transfer.

- Production must lead sales: what sells at 11:00 was cooked before 11:00. The plan has to carry that shift, not leave it to crew intuition.

3. Goals

- One flow — **Setup -> targets -> Submit** — planning every plannable template for one branch × date.
- **Autofill (automatic on valid Setup)**: reference-day sales (excluding LSM, Birthday, Event, Big Order — PP-04) counted through each template's members × Qty BOM, distributed to slots by the reference day's own profile, **shifted -1h for Hourly templates**; multi-output templates split across eligible outputs (V1: even split, no data-team dependency; reference-mix weighting is a fast-follow — §9).
- **Every slot editable before submit**; zero = skip.
- **Raw Material visibility at produced-output level per template** — read-only, computed against *effectively available*, never blocking.
- **Submit is the single trigger**: lock + definition snapshot + Production Order creation (per-slot — §5.4, flagged).

4. Plan Writes Intent Only — No Stock, Never Forces the Actual

The plan is a statement of intent, not a stock document. It writes no movement on create, edit, submit, or delete. Deduction belongs to the exits (EPIC 2); production banks onto the produced output at the actual entry (3.1); the actual recorded against the plan is **never forced to match** — above, below, or on plan are all valid, and the entries stay editable until each window's close + 3h (3.1). Divergence is the report's subject (PP-12), not an error state.

The Raw Material step **reads** stock — it never writes, reserves, or commits. Reserving material for a plan would be a phantom deduction and is explicitly rejected. Stock-coverage enforcement (the BRD's PP-15 input block) is **anticipated here** — the shortfall flag routes the SM to GR/Transfer ahead of the cook day — and deliberately **not** re-enforced at the actual entry (deviation, §9).

5. System Flow & Behavior

5.1 Setup — branch, dates, source

The form opens from the tableview (" + New Production Plan"):

Field	Required	Notes
Branch	Yes auto	The SM's assigned branch; disabled
Tanggal Planning	Yes	Today or future; one plan per branch per date; no retroactive planning
Tanggal Acuan	Yes auto	Computed: same day-of-week, same week-of-month, previous month (Senin W2 → Senin W2 bulan sebelumnya, PP-05.1.d). Overridable with another past date, bounded to the allowed range (~2 months back) — shown as a banner ("Tanggal acuan hanya bisa digunakan antara [range]")
POS	Yes	Sales source; Default

No cycle is asked — each template brings its own Tipe (3.3). A plan date simply contains all plannable templates, Daypart and Hourly together. **Daily Target Sales and Buffer are not part of V1 Setup** — both are deferred with generation (§9).

5.2 Autofill — through the template mapping, automatic

As soon as Setup is valid (branch + both dates), the page **automatically** computes, per plannable template (3.3 §5.3 gate) — no manual trigger. If the SM later overrides Tanggal Acuan, the autofill **recomputes on that change** (and re-freezes the split, step 4); stale numbers are never left behind.

- **Pull and clean the reference day's sales** (menu level, POS source):
- **Exclude flagged transaction types** — LSM, Birthday, Event, Big Order — from the day's totals (PP-04); the day is kept, only those lines drop.
- **Fall back if the day itself is unusable** — if the reference day is flagged as an event/holiday, or the excluded types dominate it so what remains isn't a representative day, step back **one month** to the same weekday / week-of-month and retry, capped at the **~2-month acuan bound**. This reuses the acuan-range logic already in Setup — it is a date-stepping loop over data the plan already reads, **no data-team dependency**.
- **Count demand through the members**: each member menu's sold pcs × its **Qty BOM** → the template's unit; summed across members = the template's reference-day total. Menus are never planned independently — the template is the plan line. A produced-SFG template resolves the same way: its members are menus, and Qty BOM converts menu pcs to the template's unit through the BOM chain.
- **Distribute to slots by the reference day's own profile** — Hourly: per clock-hour wave, **shifted one hour earlier** (sales at hour H → plan cook at H-1; PP-11's layout: 10–11 cooks for Lunch-opening 11:00); Daypart: summed into the template's windows, with the derived **batch** (grams ÷ BOM qty-per-batch — the BRD's *Suggestion Freq Batch*; shown, not typed).
- **Multi-output templates (Daypart only)**: the template total splits across its outputs per 3.3 §4's rule — eligible-gated, redistribution on ineligibility, one-takes-all. **V1 ships the even-split path** (total ÷ eligible outputs) — app-side, **no data-team dependency**. The **reference-mix weighting** (cook more of what sold more) is a **fast-follow that lands when the per-output reference pipeline is proven** (data-team owned — §9); until then, even split is the live behavior. Either way the split is **frozen at generation** (recomputed only if a Setup input — the acuan date — changes); per-output allocations are shown under the template row.
- **Buffer is deferred entirely — no buffer columns in V1**. The Suggest Buffer / Buffer lever, its computation ($(\text{target acuan} \div \text{target planning}) \times 100$), and the Daily Target it reads all arrive with 3.4's generation; when they do, they recompute **in-page automatically** — never via a manual trigger. Buffer will affect the following day's plan only (§9).

Every filled slot is editable before submit — the autofill is a proposal; the SM owns the shape. **Zero = skip**: a zeroed slot cooks nothing; a template left entirely at zero produces no Production Order line (helper: *"Item dengan qty 0 tidak akan diproduksi dan tidak masuk production order."*).

5.3 Raw Material — see the draw, read-only, output-grain

Before submitting, the SM sees what the plan will pull, grouped **at produced-output level per template** — SKIN shows Chicken Skin's requirement; Fruit Tea shows its three output lines per the split — exploded to immediate components via the BOM. Never per-menu; PM never appears (packaging deducts at sale).

- **"Available" is computed honestly**: under exit-only the raw book reads high intraday by design (recipe content locked in cooked-but-unexited goods), so the figure is **effectively available = book – outstanding**, read from 3.1's used/outstanding/current engine. Presentation unchanged — one figure per component, no ledger columns (Option B); optional caption ("excludes stock committed in prepared items").
- **Read-only, never blocking** — short components surface first with shortfall quantities; the call-to-action routes to **Goods Receipt / Internal Transfer**; no PR/PO. This is where the BRD's stock-coverage intent (PP-15) is enforced — ahead of the cook day, not at the entry.
- Per-plan scope (this date); no cross-date accumulation in V1 (§9).

5.4 Submit — lock, snapshot, and create the Production Orders

Submit does three things atomically: **locks** the plan (immutable thereafter), **snapshots** its definitions (template versions, output sets, member Qty BOMs, windows, the output split), and **creates the Production Orders**.

Working assumption — one Production Order per slot (! pending PM confirmation, §9). The plan breaks into **one order per Daypart window and one per Hourly wave** (PRODO-0001 = Breakfast, PRODO-0002 = Lunch, ... PRODO-0004+ = the hourly waves), each carrying that slot's template lines (and per-output allocations for multi-output templates). Orders carry status **In queue -> Cooking -> Ready**; earlier orders complete, the current one cooks, later orders **auto-dispatch to the KDS at their slot time** (surfacing Pending 1h before — 3.1). If the ruling lands as one-order-per-plan instead, §5.4/§5.5 and 3.1's capture grain adjust; nothing else in this PRD changes.

Corrections to what actually happens flow through 3.1 (entries editable until window close + 3h), never through plan edits.

5.5 The tableview

One row per plan — date, branch, tanggal acuan, and progress **reflected from its Production Orders** (overall % and per-order status). Clicking a submitted plan opens its read-only snapshot with the order breakdown (per-slot orders, per-template progress, tap-through to per-output lines); an unsubmitted session resumes the form. Order statuses and completion semantics are owned by the Production Order contract (3.1/KDS); this view consumes them.

5.6 Roles

The flow is the SM's (branch auto-locked). Crew never author plans — their surface is the KDS (3.1). HO authors templates (3.3), not outlet plans. V1 cannot hard-enforce roles (QSR role-management pending); procedural, changes stamped.

6. Data Model (reshaped)

Entity / Field	Notes
production_plan	One per branch × date: plant_id, planning_date, reference_date (+ range validation), pos_source, status (draft / submitted), definition_snapshot (jsonb: template versions, output sets, Qty BOMs, windows, output split)
production_plan_line	One per template × slot : template_id, slot (wave or window), quantity (template UoM), derived batch_count (Daypart)
production_plan_fg_alloc	Multi-output only: one per line × output — the frozen split (line_id, product_variant_id — FG or produced SFG , allocated_qty). Table name retained for continuity (3.3 §9)
production_order	Per-slot (flagged §9) : one per plan × slot — plan_id, slot, status (IN_QUEUE / COOKING / READY), dispatched-at; lines mirror the plan lines for that slot
Buffer fields	suggest_buffer_pct, buffer_pct — deferred, not in V1 (arrive with 3.4's generation)

No movement tables are touched. basis, the plan-level cycle, and the Menu-level revenue entities from rev 53 are retired.

7. User Stories & Acceptance Criteria

Story 1 — Setup fixes the branch and dates; the day autofills (PP-04, PP-05)

As an SM, I start a plan by fixing which branch and which dates it's for — my branch already filled in, the reference day already computed — and every template immediately fills with cook quantities drawn from that comparable day, counted through its menus, spread across the day, and shifted so I cook before I sell.

Acceptance Criteria

- Branch autofills from the SM's assignment and is disabled (not selectable).
- Only one plan may exist per branch per date; starting a second for the same date reopens the existing plan (or its draft session) instead of creating a duplicate.
- Tanggal Planning is today or a future date; retroactive planning is refused.
- Tanggal Acuan is computed as same day-of-week, same week-of-month, previous month (PP-05.1.d) and displayed; the SM may override it with another past date, but only within the allowed range (~2 months back), shown as a banner.
- POS source is captured. **Daily Target Sales is not part of V1** — it is deferred with buffer/generation (§9).
- **The autofill runs automatically once Setup is valid — no button.** For each plannable template (3.3 §5.3 gate), demand = Σ over its member menus of (sold pcs $\times$ that member's Qty BOM), in the template's UoM, from the reference day's sales, **excluding transaction types LSM, Birthday, Event, and Big Order** (PP-04). Member menus are never planned as their own lines.
- Quantities distribute to slots by the reference day's own profile: Hourly templates per clock-hour wave, Daypart templates summed into the template's windows with the derived batch (grams $\div$ BOM qty-per-batch, shown not typed).
- Hourly templates are **shifted one hour earlier** — reference sales in hour H fill the H-1 cook wave (PP-11 layout).
- If the SM overrides Tanggal Acuan, the autofill **recomputes on that change**; stale numbers are never left behind. Only plannable templates appear; an unplannable one is surfaced at its template (3.3), not silently dropped.

Scenario: Branch locked, reference computed, day filled
Given the SM is assigned to RF Kemang and starts a plan for Monday (week 2)
Then Branch shows RF Kemang, disabled
And Tanggal Acuan defaults to Monday of week 2 in the previous month
And every plannable template fills automatically from that day's sales

Scenario: One plan per branch per date
Given a plan already exists for Friday at RF Kemang
When the SM starts a new plan for Friday
Then creation is refused and the existing plan (or its draft session) opens

Scenario: Acuan outside the allowed range is rejected
Given the allowed range is 2026-05-24 to 2026-07-24
When the SM overrides Tanggal Acuan to 2026-04-01
Then the date is rejected and the range banner is shown

Scenario: SKIN fills as one line, converted and shifted
Given SKIN's members sold 120 pcs on the reference day, 30 of them in the 11:00 hour
Then SKIN shows one Hourly row totaling 120 $\times$ its members' Qty BOM in template units
And the 30 pcs from the 11:00 hour appear in the 10:00 cook wave

Scenario: Excluded transaction types don't inflate demand
Given the reference day includes a Big Order of 200 pcs of a SKIN member
Then that 200 pcs is excluded from SKIN's computed demand

Story 2 — The SM edits slots before submit; zero skips (PP-07 lever, deviation)

As an SM, the autofill is a starting point — I reshape any slot for what I know about today, and a slot I set to zero simply isn't cooked.

Acceptance Criteria

- Every autofilled slot is editable before submit; a template's day total recomputes live as slots change.
- Zero = skip: a zeroed slot cooks nothing; a template left entirely at zero produces no Production Order line; the static helper line is shown ("**Item dengan qty 0 tidak akan diproduksi dan tidak masuk production order.**").
- No per-row skip toggle and no cap on over-entry — the SM may set any slot above or below the autofill.

Scenario: Override a wave, day total follows
Given Spicy Chicken autofilled 12 pcs in the 15:00 wave and 240 pcs for the day
When the SM changes the 15:00 wave to 20
Then the day total updates to 248

Scenario: A fully-zeroed template produces no order line
Given the SM sets every slot of a template to 0
When the plan is submitted
Then that template yields no Production Order line

Story 3 — Multi-output split is visible and editable (3.3 §4 split rule)

As an SM, a multi-output template like Fruit Tea plans one total, but I can see how it lands across its premixes — and the split respects what's actually in stock.

Acceptance Criteria

- A multi-output template row expands to its per-output allocations per 3.3 §4's rule: **V1 = even split across eligible outputs** (eligible = has stock / not removed; ineligible share redistributes in ratio; one eligible output takes the full total). **Reference-mix weighting is a fast-follow** gated on the per-output data pipeline (§9).
- The split is frozen when the autofill runs; it recomputes only if a Setup input (the acuan date) changes.
- An output with zero stock or removed from the template when the autofill runs is ineligible and receives 0, its share redistributed.
- The template's slotted totals stay editable; edits re-apply the frozen split proportions unless the acuan date changes and the autofill recomputes.
- Multi-output templates are Daypart only (3.3) — no Hourly multi-output row can arise here.

Scenario: V1 even split across eligible outputs
Given Fruit Tea totals 90 with three eligible outputs (Pomelo, Blackcurrant, Jasmine Tea)
When the plan autofills
Then the allocation shows 30 / 30 / 30

Scenario: Ineligible output redistributes (even)
Given Fruit Tea totals 90 and Jasmine Tea has zero stock when the plan autofills
Then the allocation shows Pomelo 45 / Blackcurrant 45 / Jasmine Tea 0

Scenario: Reference-mix weighting (fast-follow, when the per-output pipeline is live)
Given the pipeline supplies reference mix Pomelo 45 / Blackcurrant 40 / Jasmine Tea 15 for a total of 100
Then the allocation shows Pomelo 45 / Blackcurrant 40 / Jasmine Tea 15

Story 4 — Raw Material shows the draw without gating (exit-only, effectively-available)

As an SM, I see what my plan will pull from stock — per produced output, per template — and what's short, before I commit, so I can arrange a GR or transfer ahead of the cook day instead of discovering it at the fryer.

Acceptance Criteria

- The step shows each planned template's requirement grouped at produced-output level (SKIN → Chicken Skin; Fruit Tea → its three outputs per the split), exploded to immediate components via the BOM; grouping is never per menu.
- PM never appears (packaging deducts at sale, not production).
- "Available" is **effectively available = book – outstanding** (read from 3.1's used/outstanding/current engine), shown as one figure per component with no ledger columns; an optional caption may note it excludes stock committed in prepared items.
- Short components surface first with their shortfall quantity and a route to Goods Receipt / Internal Transfer; no PR/PO is raised.
- The step never blocks proceeding or submitting; the check is per plan (this date) — no cross-date accumulation in V1.

Scenario: A short component is visible, not blocking
Given Fruit Tea's Pomelo allocation needs 5 kg premix beyond effectively available
When the SM reaches the Raw Material step
Then Pomelo premix appears first, flagged "short 5 kg", routed to GR / Transfer
And the SM can still proceed and submit

Scenario: Available reflects committed stock honestly
Given 40 kg of a component is on the book but 15 kg is committed in cooked-but-unexited goods
Then the step shows 25 kg available for that component, not 40 kg

Story 5 — Submit locks, snapshots, and creates the per-slot orders

As an SM, submitting is the moment of commitment — the plan freezes, and the kitchen gets its orders, one per slot, dispatched as their time comes.

Acceptance Criteria

- Submit atomically: locks the plan (immutable — no edit, no delete), freezes the definition snapshot (template versions, output sets, member Qty BOMs, windows, the frozen output split), and creates the Production Orders.
- **One Production Order per slot** — one per Daypart window and one per Hourly wave — each carrying that slot's template lines and per-output allocations (! per-slot grain pending confirmation, §9).
- Orders carry status In queue → Cooking → Ready; later orders auto-dispatch to the KDS at their slot time (surfacing Pending 1h before — 3.1).
- A submitted plan cannot be edited or deleted; corrections to what actually happened flow through 3.1, never plan edits.
- A later template or registry edit never reaches a submitted plan (forward-only, carried by the snapshot).

Scenario: Per-slot orders from one plan
Given a submitted plan with Daypart templates over 3 windows and one Hourly template over 14 active waves
When the SM submits
Then one Production Order is created per window and per wave, each with its slot's lines
And each order dispatches to the KDS at its slot time

Scenario: Template edit doesn't reach a submitted plan
Given a submitted plan built on Fruit Tea with three outputs
When HO removes an output from the Fruit Tea template today
Then the submitted plan still carries three outputs; tomorrow's new plan carries two

Story 6 — The plan list and its detail (PP-06)

As an SM, I have one home screen showing every plan I've made, its progress, and a way into the full breakdown — so I can track the day at a glance and drill in when I need to.

Acceptance Criteria

- The tableview lists plans with: branch code / name, Tanggal Planning, Tanggal Acuan, per-template total production for that date, created date / by, and a Klik Detail action (PP-06.2).
- Each row shows progress reflected from its Production Orders — overall % and per-order status (In queue / Cooking / Ready).
- Klik Detail opens the plan's read-only detail: the per-slot order breakdown, per-template progress, and tap-through to per-output lines for multi-output templates.
- Filter and search are available (PP-06.4).
- Status and completion semantics are owned by the Production Order contract (3.1/KDS); this view only consumes them.

Scenario: List reflects live order progress
Given a submitted plan whose Breakfast order is Ready and Lunch order is Cooking
When the SM opens the plan list
Then the plan's row shows partial progress with per-order statuses Ready and Cooking

Scenario: Detail drills to per-output lines
Given a submitted plan containing Fruit Tea
When the SM clicks Detail and expands Fruit Tea
Then Honey Pomelo, Blackcurrant, and Jasmine Tea each show their planned quantity

Story 7 — A draft plan resumes or is discarded

As an SM, I can start a plan, step away, and come back to it — or throw it away — without any of it touching stock, because nothing is committed until I submit.

Acceptance Criteria

- A plan in progress (Setup done, or autofilled but not submitted) is saved as a draft and resumable for the same branch/date.
- Resuming reopens the form with its state — autofilled quantities and edits intact; changing the acuan date recomputes the autofill, otherwise the SM continues editing.
- A draft may be discarded freely — no stock movement, PR/PO, or Production Order was ever written.
- Only a submitted plan is immutable; a draft carries no downstream effect until submit.

Scenario: Resume an autofilled-but-unsubmitted plan
Given the SM autofilled a plan for tomorrow and left without submitting
When the SM returns and opens tomorrow's plan
Then the autofilled quantities are restored and remain editable

Scenario: Discard a draft leaves no trace
Given an unsubmitted draft plan
When the SM discards it
Then no Production Order and no stock movement exist for it

8. Dependencies

Dependency	**Direction**	**Note**
PRD 3.3 — Planning Template	upstream	The plannable gate; members × Qty BOM; Tipe per template; the split rule this PRD implements; produced output = FG or produced SFG
EPIC 2 BOM + exit engine	upstream	Qty BOM conversions; immediate-component explosion for the

Dependency	**Direction**	**Note**
		preview; deduction fires at sale/waste, never here
Sales history (POS)	upstream	Reference-day sales at menu level, type exclusions (PP-04), hourly profile
PRD 3.1 — Actual entry	sibling	Captures against the orders this submit creates; defines the used/outstanding/current engine §5.3 reads
Production Order / KDS contract	downstream sibling	Per-slot order statuses, auto-dispatch, Pending-1h surfacing — owned there, created through it here
Goods Receipt / Internal Transfer	upstream	The Raw Material step's routing targets; routing only
Data team — per-output reference mix	upstream	The split's weighting input; even split is the zero-dependency fallback (3.3 §9)
PRD 3.4 — Generation (deferred)	downstream	H+7 generation, Suggest Buffer computation + Generate, forecast-fed Daily Target — land there and surface through this form's inert fields

9. Risks & Assumptions

Item	Type	Severity	Note
One Production Order per slot	! OPEN — working assumption, pending PM ruling	High	Adopted from the validated prototype (PRODO-0001 Breakfast, per-wave hourly; In queue → Cooking → Ready; auto-dispatch at slot time). If ruled as one-order-per-plan instead, §5.4/§5.5/§6 and 3.1's capture grain adjust. Decide before the eng handoff
Produced SFG plans identically to an FG	Decided (PM, 28 Jul)	—	Per 3.3 §9. A produced SFG (BOM-bearing intermediate; the BBQ Sauce levels) sits on its own template, so it gets its own plan lines, slotted totals and Production Order lines. The autofill is unchanged — its members are still menus and Qty BOM resolves menu pcs → the output's unit through the BOM chain, in the same single pass, with the same cleaning and -1h Hourly shift. No data-team input. Folded into §5/§6/§7 rather than carried as a separate section
A produced SFG can appear twice in one plan	! OPEN — pending PM ruling	Medium	Where a produced-SFG template is planned on the same date as an FG template that consumes it, the SFG appears both as its own plan line (being made today) and inside the parent's Raw Material

Item	Type	Severity	Note
			requirement (needed today). Whether §5.3 nets the two, separates "being made today" from "must be received", or ships as-is is not ruled . Decide before the eng handoff
Revenue basis deferred	Decided (user feedback #2/#7, 27 Jul)	—	The rev-53 two-basis wizard (Revenue plans Menus, §5.2a/§5.4a, reconciliation panel) is retired from V1; revenue enters later as the target→Suggest-Buffer lever, not a parallel path. Menu Master seam drops off the V1 critical path
Buffer + Daily Target + generation deferred (platform-first)	Decided (PM, 28 Jul)	—	V1 builds the core platform only — no buffer columns and no Daily Target field in the UI or schema. Suggest Buffer/Buffer computation $((\text{target acuan} \div \text{target planning}) \times 100)$, the Daily Target it reads, Generate, and H+7 all land with 3.4 (PP-05/07 deferred — Kevina register)
Reference-day cleaning = exclude flagged types, then step back a month if the day is unusable	Decided (PM, 27 Jul)	—	PP-04 excludes LSM/Birthday/Event/Big Order lines from the day; if the day itself is an event/holiday or the exclusions gut it, step back one month (capped at the ~2-month acuan bound) to a cleaner comparable day. Date-stepping over data the plan already reads — no data-team dependency
Slots editable before submit	Decided (16 Jul, re-affirmed)	—	The BRD's only lever is buffer-then-Generate; manual V1 keeps every slot editable — deviation carried to Kevina
-1h shift applies to Hourly only	Assumption	Low	PP-11's cook-hour layout shows the shift on hourly waves; Daypart windows already lead by construction (window opens before its demand). Confirm with ops if Daypart needs an explicit lead too
Split frozen at generation	Decision (3.3 §9 companion)	Low	Eligibility reads stock, so regeneration could shift allocations intraday; freezing at generation keeps the plan stable — it recomputes only if the acuan date changes
PP-15 enforced at planning, not entry	Decided (22 Jul)	Medium	The GR hard block moves to this PRD's shortfall routing; the actual entry never stock-gates. Deviation for Kevina
Daily Target deferred (not in V1)	Decided (PM, 28 Jul)	—	The field only ever fed the deferred buffer/revenue lever, so it leaves V1 entirely; it returns with 3.4 (forecast-fed)
Cumulative horizon check dropped	Conscious regression (carried)	Medium	Per-plan check only; Tuesday's plan eating Wednesday's stock isn't flagged in V1
Role not enforced in V1	Assumption	Medium	Procedural until QSR role-management ships
